#### 1. Introduction

Let  $L/\mathbb{Q}$  be a Galois extension with group

$$D_3 = \langle \sigma, \tau : \sigma^3 = \tau^2 = \tau \sigma \tau \sigma = 1 \rangle,$$

the dihedral group of order 6. Then  $L/\mathbb{Q}$  admits a canonical non-classical Hopf-Galois structure with Hopf algebra  $H_{\lambda}$ .

By a theorem of C. Greither,  $H_{\lambda} \cong \mathbb{Q}[D_3]$  as  $\mathbb{Q}$ -algebras.

In this talk we show that up to scalar multiplication, nilpotent elements in  $H_{\lambda}$  correspond to rational points on a certain conic over  $\mathbb{Q}$ . Using this we give a new proof of Greither's theorem.

### 2. Hopf-Galois Theory

We review some of the basic notions of Hopf-Galois theory.

Let L be a finite extension of a field K.

Let *H* be a finite dimensional, cocommutative *K*-Hopf algebra with comultiplication  $\Delta : H \to H \otimes_R H$ , counit  $\varepsilon : H \to K$ , and coinverse  $S : H \to H$ .

Suppose there is a K-linear action of H on L that satisfies

$$h \cdot (xy) = \sum_{(h)} (h_{(1)} \cdot x)(h_{(2)} \cdot y)$$
$$h \cdot 1 = \varepsilon(h)1$$

for all  $h \in H$ ,  $x, y \in L$ , where  $\Delta(h) = \sum_{(h)} h_{(1)} \otimes h_{(2)}$  is Sweedler notation.

Suppose also, that the K-linear map

$$j: L \otimes_{\mathcal{K}} H \to \operatorname{End}_{\mathcal{K}}(L), \ j(x \otimes h)(y) = x(h \cdot y)$$

is an isomorphism of vector spaces over K. Then H together with this action provides a *Hopf-Galois structure* on L/K.

**Example 2.1.** Suppose L/K is Galois with group G. Let H = K[G] be the group algebra, which is a Hopf algebra via  $\Delta(g) = g \otimes g$ ,  $\varepsilon(g) = 1$ ,  $S(g) = g^{-1}$ , for all  $g \in G$ . The action of K[G] on L given as

$$\left(\sum_{g\in G} r_g g\right) \cdot x = \sum_{g\in G} r_g(g(x))$$

provides the "usual" Hopf-Galois structure on L/K which we call the *classical* Hopf-Galois structure.

In the case that L/K is separable, C. Greither and B. Pareigis have given a complete classification of Hopf-Galois structures.

Let L/K be separable with normal closure E. Let  $G = \operatorname{Gal}(E/K)$ ,  $G' = \operatorname{Gal}(E/L)$ , and X = G/G'. Denote by  $\operatorname{Perm}(X)$  the group of permutations of X. A subgroup  $N \leq \operatorname{Perm}(X)$  is *regular* if |N| = |X| and  $\eta[xG'] \neq xG'$  for all  $\eta \neq 1_N, xG' \in X$ .

Let  $\lambda : G \to \operatorname{Perm}(X)$ ,  $\lambda(g)(xG') = gxG'$ , denote the left translation map. A subgroup  $N \leq \operatorname{Perm}(X)$  is *normalized* by  $\lambda(G) \leq \operatorname{Perm}(X)$  if  $\lambda(G)$  is contained in the normalizer of N in  $\operatorname{Perm}(X)$ .

**Theorem 2.2** (Greither-Pareigis). Let L/K be a finite separable extension. There is a one-to-one correspondence between Hopf Galois structures on L/K and regular subgroups of Perm(X) that are normalized by  $\lambda(G)$ .

One direction of this correspondence works by Galois descent: Let N be a regular subgroup normalized by  $\lambda(G)$ . Then G acts on the group algebra E[N] through the Galois action on E and conjugation by  $\lambda(G)$  on N, i.e.,

$$g(x\eta) = g(x)(\lambda(g)\eta\lambda(g^{-1})), \ g \in G, \ x \in E, \ \eta \in N.$$

We then define

$$H = (E[N])^G = \{x \in E[N] : g(x) = x, \forall g \in G\}.$$

The action of H on L/K is thus

$$\left(\sum_{\eta\in N}r_{\eta}\eta\right)\cdot x=\sum_{\eta\in N}r_{\eta}\eta^{-1}[1_{G}](x).$$

The fixed ring H is an n-dimensional K-Hopf algebra, n = [L : K], and L/K has a Hopf Galois structure via H.

Moreover,

$$E \otimes_{\mathcal{K}} H \cong E \otimes_{\mathcal{K}} \mathcal{K}[N] \cong E[N],$$

as E-Hopf algebras, that is, H is an E-form of K[N].

Theorem 2.2 can be applied to the case where L/K is Galois with group G (thus, E = L,  $G' = 1_G$ , G/G' = G).

In this case the Hopf Galois structures on L/K correspond to regular subgroups of Perm(G) normalized by  $\lambda(G)$ , where  $\lambda: G \to Perm(G), \lambda(g)(h) = gh$ , is the left regular representation.

**Example 2.3.** Suppose L/K is a Galois extension,  $G = \operatorname{Gal}(L/K)$ . Let  $\rho : G \to \operatorname{Perm}(G)$  be the right regular representation defined as  $\rho(g)(h) = hg^{-1}$  for  $g, h \in G$ . Then  $N = \rho(G)$  is a regular subgroup normalized by  $\lambda(G)$ , since  $\lambda(g)\rho(h)\lambda(g^{-1}) = \rho(h)$  for all  $g, h \in G$ .

 $N = \rho(G)$  corresponds to a Hopf-Galois structure with K-Hopf algebra

$$H_{\rho} = (L[\rho(G)])^{G} = K[G],$$

the usual group ring Hopf algebra with its usual action on L. Consequently,  $\rho(G)$  corresponds to the *classical* Hopf Galois structure. **Example 2.4.** Again, suppose L/K is Galois with group G. Let  $N = \lambda(G)$ .

Then N is a regular subgroup of Perm(G) which is normalized by  $\lambda(G)$ , and  $N = \rho(G)$  if and only if N abelian. The corresponding Hopf algebra is the fixed ring

$$H_{\lambda} = (L[\lambda(G)])^{G}.$$

If G is non-abelian, then  $N = \lambda(G)$  corresponds to the *canonical* non-classical Hopf-Galois structure.

3. The Case  $K = \mathbb{Q}$ ,  $G = D_3$ 

For the remainder of this talk, we specialize to the case where the base field  $K = \mathbb{Q}$ , and the Galois group is the dihedral group of order 6,

$$D_3 = \langle \sigma, \tau : \sigma^3 = \tau^2 = \sigma \tau \sigma \tau = 1 \rangle.$$

Let  $L/\mathbb{Q}$  be a Galois extension with group  $D_3$ . By Example 2.3, and Example 2.4, we have regular subgroups  $\rho(D_3)$ ,  $\lambda(D_3)$  normalized by  $\lambda(D_3)$ .

These regular subgroups give rise to the classical and canonical non-classical Hopf-Galois structures on  $L/\mathbb{Q}$  via the  $\mathbb{Q}$ -Hopf algebras  $\mathbb{Q}[D_3]$  and  $H_{\lambda}$ , respectively.

The classical Hopf-Galois structure on  $L/\mathbb{Q}$  has  $\mathbb{Q}$ -Hopf algebra  $\mathbb{Q}[D_3] = \{a_{0,0} + a_{0,1}\sigma + a_{0,2}\sigma^2 + a_{1,0}\tau + a_{1,1}\tau\sigma + a_{1,2}\tau\sigma^2 : a_{i,j} \in \mathbb{Q}\}.$ 

And, due to L. Childs, the canonical non-classical Hopf-Galois structure on  $L/\mathbb{Q}$  has  $\mathbb{Q}$ -Hopf algebra

$$egin{aligned} \mathcal{H}_{\lambda} &= \{ a_0 + a_1 \sigma + au(a_1) \sigma^2 + b_0 au + \sigma(b_0) au \sigma + \sigma^2(b_0) au \sigma^2 : \ &a_0 \in \mathbb{Q}, a_1 \in L^{\langle \sigma 
angle}, b_0 \in L^{\langle au 
angle} \} \end{aligned}$$

・ロト ・ 目 ・ ・ ヨト ・ ヨ ・ うへつ

It is of interest to determine how  $\mathbb{Q}[D_3]$  and  $H_{\lambda}$  fall into isomorphism classes as algebras and Hopf algebras.

**Proposition 3.1.**  $H_{\lambda}$  and  $\mathbb{Q}[D_3]$  are not isomorphic as  $\mathbb{Q}$ -Hopf algebras.

Proof. See [KKTU19, Proposition 4].

The situation is different as algebras.

**Theorem 3.2.** [C. Greither]  $H_{\lambda} \cong \mathbb{Q}[D_3]$  as  $\mathbb{Q}$ -algebras.

**Proof.** This is shown in [KKTU19, Theorem 4]. Note: Greither's theorem holds for any Galois extension L/K,  $\mathbb{Q} \subseteq K$ , with group G, that is, we always have  $H_{\lambda} \cong K[G]$  as K-algebras.

Since  $\mathbb{Q}$  has characteristic 0, both  $H_{\lambda}$  and  $\mathbb{Q}[D_3]$  are left semisimple and decompose into a product of matrix rings over division rings.

By [CR81, Example (7.39)],  $\mathbb{Q}[D_3] \cong \mathbb{Q} \times \mathbb{Q} \times \operatorname{Mat}_2(\mathbb{Q}),$ as  $\mathbb{Q}$ -algebras. And so, by Theorem 3.2  $H_{\lambda} \cong \mathbb{Q} \times \mathbb{Q} \times \operatorname{Mat}_2(\mathbb{Q}),$  (1)

as  $\mathbb{Q}$ -algebras.

Let M be the subalgebra of  $H_{\lambda}$  corresponding to the component  $Mat_2(\mathbb{Q})$  in the decomposition (1).

We compute a  $\mathbb{Q}$ -basis for  $M \subseteq H_{\lambda}$ .

Let  $\alpha \in L$  be so that  $L^{\langle \sigma \rangle} = \mathbb{Q}(\alpha)$ ,  $\alpha^2 \in \mathbb{Q}$ , and let  $a_1 = q_0 + q_1 \alpha$ be a typical element of  $\mathbb{Q}(\alpha)$ ,  $q_0, q_1 \in \mathbb{Q}$ . Note that  $\tau(a_1) = q_0 - q_1 \alpha$ .

Let  $\beta \in L$  be so that  $L^{\langle \tau \rangle} = \mathbb{Q}(\beta)$  with  $b_0 = r_0 + r_1\beta + r_2\beta^2$  a typical element of  $\mathbb{Q}(\beta)$ ,  $r_0, r_1, r_2 \in \mathbb{Q}$ .

Let 
$$v = 2\beta - \sigma(\beta) - \sigma^2(\beta)$$
,  $w = 2\beta^2 - \sigma(\beta^2) - \sigma^2(\beta^2)$ .

**Proposition 3.3.** A  $\mathbb{Q}$ -basis for M is

$$\left\{\frac{2-\sigma-\sigma^2}{3}, \alpha(\sigma-\sigma^2), \frac{v\tau+\sigma(v)\tau\sigma+\sigma^2(v)\tau\sigma^2}{3}, \frac{w\tau+\sigma(w)\tau\sigma+\sigma^2(w)\tau\sigma^2}{3}\right\}.$$

**Proof.** The element  $e_3 = (2 - \sigma - \sigma^2)/3$  is the orthogonal idempotent corresponding to the component  $Mat_2(\mathbb{Q})$  in the decomposition (1). By Childs' result,  $H_{\lambda}$  consists of elements of the form

$$h = a_0 + a_1\sigma + \tau(a_1)\sigma^2 + b_0\tau + \sigma(b_0)\tau\sigma + \sigma^2(b_0)\tau\sigma^2,$$

where  $a_0 \in \mathbb{Q}$ ,  $a_1 \in \mathbb{Q}(\alpha)$ , and  $b_0 \in \mathbb{Q}(\beta)$ . Thus, the product  $e_3h$  is a typical element of M, which can be written as a linear combination of the claimed basis.

Since  $Mat_2(\mathbb{Q})$  has nilpotent elements, e.g.  $\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$ ,  $H_{\lambda}$  must have nilpotent elements, necessarily in the subalgebra M.

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・ うへぐ

Here is how we find them.

Let  $m \in M \subseteq H_{\lambda}$ . By Proposition 3.3, there exists  $a, b, c, d \in \mathbb{Q}$  so that

$$m = a(2 - \sigma - \sigma^{2}) + b\alpha(\sigma - \sigma^{2}) + c(v\tau + \sigma(v)\tau\sigma + \sigma^{2}(v)\tau\sigma^{2}) + d(w\tau + \sigma(w)\tau\sigma + \sigma^{2}(w)\tau\sigma^{2}) = a(2 - \sigma - \sigma^{2}) + b\alpha(\sigma - \sigma^{2}) + ((cv + dw)\tau + \sigma(cv + dw)\tau\sigma + \sigma^{2}(cv + dw)\tau\sigma^{2}).$$

Let  $\operatorname{Tr}_{L^{\langle \tau \rangle}/\mathbb{Q}} : L^{\langle \tau \rangle} \to \mathbb{Q}$  and  $\operatorname{Tr}_{L^{\langle \sigma \tau \rangle}/\mathbb{Q}} : L^{\langle \sigma \tau \rangle} \to \mathbb{Q}$  and denote the trace maps. Let  $\operatorname{N}_{L^{\langle \tau \rangle}/\mathbb{Q}} : L^{\langle \tau \rangle} \to \mathbb{Q}$  denote the norm map.

**Lemma 3.4.** The element *m* is nilpotent of index 2 if and only if the following conditions hold:

**Proof.** We show directly that  $m^2 = 0$  if and only if conditions (i), (ii), and (iii) hold.

## 4. Application to Binary Quadratic Forms

Let  $p(X) = X^3 + qX + r$  be an irreducible cubic over  $\mathbb{Q}$  with discriminant  $\mathcal{D} = -4q^3 - 27r^2$ . Without loss of generality we can assume that  $q, r \in \mathbb{Z}$ .

Suppose  $\mathcal{D}$  is not a square in  $\mathbb{Q}$ . Then the splitting field L of p(X) is Galois over  $\mathbb{Q}$  with group  $D_3$ .

By [Ro15, Proposition A-5.69],  $L^{\langle \sigma \rangle} = \mathbb{Q}(\sqrt{\mathcal{D}})$ .

By [Ro15, Theorem A-1.2], the roots of p(X) are

$$s+t$$
,  $s\zeta + t\zeta^2$ ,  $s\zeta^2 + t\zeta$ 

with  $s = \sqrt[3]{(-r + \sqrt{R})/2}$ , t = -q/(3s),  $R = r^2 + (4/27)q^3$ , and  $\zeta$  a primitive 3rd root of unity. Note that st = -q/3 and  $s^3 + t^3 = -r$ .

 ・

The Galois action on L is defined by

$$\begin{aligned} \sigma(s+t) &= s\zeta + t\zeta^2, \quad \sigma(s\zeta + t\zeta^2) = s\zeta^2 + t\zeta, \quad \sigma(s\zeta^2 + t\zeta) = s + t, \\ \tau(s+t) &= s + t, \quad \tau(s\zeta + t\zeta^2) = s\zeta^2 + t\zeta, \quad \tau(s\zeta^2 + t\zeta) = s\zeta + t\zeta^2. \end{aligned}$$

Put 
$$\beta = s + t$$
,  $v = 2\beta - \sigma(\beta) - \sigma^2(\beta)$  and  $w = 2\beta^2 - \sigma(\beta^2) - \sigma^2(\beta^2)$ .

Let  $H_{\lambda}$  be the Q-Hopf algebra of the canonical non-classical Hopf Galois structure on  $L/\mathbb{Q}$ .

By Theorem 3.2,

$$H_{\lambda} \cong \mathbb{Q} \times \mathbb{Q} \times \operatorname{Mat}_{2}(\mathbb{Q}).$$

Let *M* be the subalgebra of  $H_{\lambda}$  isomorphic to  $Mat_2(\mathbb{Q})$ . Let *m* be a nilpotent element of *M*.

By Lemma 3.4(iii), there exist rationals x, y so that

$$\operatorname{Tr}_{L^{\langle \sigma \tau \rangle}/\mathbb{Q}}((xv + yw)\sigma(xv + yw)) = -\mathcal{D}.$$
(2)

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

We claim that the right-hand side of (2) is a binary quadratic form in x, y over  $\mathbb{Z}$ .

To prove this we first need a lemma.

Lemma 3.5.

(i) 
$$v = 3s + 3t$$
,  
(ii)  $w = 3s^2 + 3t^2$ ,  
(iii)  $\sigma(s^2 + t^2) = s^2\zeta^2 + t^2\zeta$ .  
(iv)  $\sigma(s^2\zeta + t^2\zeta^2) = s^2 + t^2$ .

#### Proposition 3.6. $\operatorname{Tr}_{L^{\langle \sigma\tau\rangle}/\mathbb{Q}}((xv+yw)\sigma(xv+yw)) = 9qx^2 + 27rxy - 3q^2y^2.$

**Proof.** We have  $(xv + yw)\sigma(xv + yw)$ 

$$= 9x^{2}(s+t)(s\zeta+t\zeta^{2}) + 9xy((s+t)(s^{2}\zeta^{2}+t^{2}\zeta) + (s^{2}+t^{2})(s\zeta+t\zeta^{2})) + 9y^{2}(s^{2}+t^{2})(s^{2}\zeta^{2}+t^{2}\zeta).$$

Now, applying  $\mathrm{Tr}_{L^{\langle\sigma\tau\rangle}/\mathbb{Q}}$  to each term above yields

$$\operatorname{Tr}_{L^{\langle \sigma \tau \rangle}/\mathbb{Q}}((xv + yw)\sigma(xv + yw)) = 9qx^2 + 27rxy - 3q^2y^2.$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Now, in view of (2) and Proposition 3.6, the equation

$$E: 9qX^2 + 27rXY - 3q^2Y^2 = -D$$

has a non-trivial solution (x, y) in the rationals (and hence an infinite number of rational solutions). The discriminant of the binary quadratic form is

$$\mathcal{D}' = (27r)^2 - 4(9q)(-3q^2) = -27\mathcal{D}.$$

If  $\mathcal{D}' > 0$ , then  $\mathcal{D} < 0$ . Thus if *E* is an hyperbola, then p(X) has one real root and two non-real complex roots. Moreover, if p(X) has three real roots, then *E* is an ellipse.

The nilpotent elements of  $H_{\lambda}$  (up to multiplication by a rational) correspond to rational points on the graph of *E*.

**Example 3.7.** Let  $q(X) = X^3 + 3X + 1$ . Then q(X) is irreducible with  $\mathcal{D} = -135$ , and so its splitting field  $L/\mathbb{Q}$  is Galois with group  $D_3$ . The roots of q(X) are

$$s+t, \quad s\zeta + t\zeta^2, \quad s\zeta^2 + t\zeta,$$
  
where  $s = \sqrt[3]{(-1+\sqrt{5})/2}, \ t = \sqrt[3]{(-1-\sqrt{5})/2}.$  In this case,  
 $E: \ 27X^2 + 27XY - 27Y^2 - 135 = 0,$ 

with D' = -27(-135) = 3645, and D = -135. Thus *E* is a hyperbola and  $X^3 + 3X + 1$  has exactly one real root.

Let 
$$\beta = s + t$$
,  $v = 2\beta - \sigma(\beta) - \sigma^2(\beta)$  and  $w = 2\beta^2 - \sigma(\beta^2) - \sigma^2(\beta^2)$ .

By inspection, (2,1) is a solution to E. Thus

$$m = \sqrt{-135}(\sigma - \sigma^2) + (2\nu + w)\tau + \sigma(2\nu + w)\tau\sigma + \sigma^2(2\nu + w)\tau\sigma^2$$

・ロト・日本・ヨト・ヨー うへの

is a nilpotent element of  $H_{\lambda}$ .

Fig. 1. Graph of hyperbola  $27X^2 + 27XY - 27Y^2 - 135 = 0$  given by  $X^3 + 3X + 1$ . The point (2,1) corresponds to the nilpotent element  $m \in H_{\lambda}$ .

# 4. Another Proof of Greither's Theorem

Let  $L/\mathbb{Q}$  be Galois with group  $D_3$  and let y be a generator for the subfield  $L^{\langle \tau \rangle}$  with minimal polynomial  $p(X) = X^3 + qX + r$  and discriminant  $\mathcal{D} = -4q^3 - 27r^2$ .

In this section we give an alternate proof of Greither's theorem (Theorem 3.2).

**Theorem 4.1.** (Greither)  $H_{\lambda} \cong \mathbb{Q}[D_3]$  as  $\mathbb{Q}$ -algebras.

Proof. By the theory of characters,

$$H_{\lambda} \cong \mathbb{Q} \times \mathbb{Q} \times \operatorname{Mat}_{r}(R),$$

where  $1 \le r \le 2$  and *R* is some division ring.

So to establish Greither's result, we show that r = 2 and  $R = \mathbb{Q}$ , and to do this it suffices to show that  $H_{\lambda}$  contains a non-trivial nilpotent element of index 2. In order prove the existence of such an element, we show that

$$E: 9qX^2 + 27rXY - 3q^2Y^2 = -\mathcal{D} = 4q^3 + 27r^2.$$

has a non-trivial solution in the rationals. Then by Proposition 3.6, there are rationals x, y not both zero with

$$\operatorname{Tr}_{L^{\langle \sigma \tau \rangle}/\mathbb{Q}}((xv + yw)\sigma(xv + yw)) = -\mathcal{D}.$$

Consequently, by Lemma 3.4(iii),  $H_{\lambda}$  contains a non-trivial nilpotent of index 2, and so the decomposition is in fact

$$H_{\lambda} \cong \mathbb{Q} \times \mathbb{Q} \times \operatorname{Mat}_2(\mathbb{Q}).$$

If q = 0, then E is easily solved since it reduces to XY = r. So we assume that  $q \neq 0$ .

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬぐ

If  $q \neq 0$ , one checks that X = 2q/3, Y = 3r/q is a non-trivial rational solution to *E*.
